

Trading Workshop Strategy Outline

Trading Strategy and Execution

- Systematize chart marking with color-coded lines for key levels (monthly, weekly, daily opens, highs, lows) and set alerts to identify significant price points without constant chart checking.
- Use filters and scans to identify potential trade opportunities based on market conditions, liquidity, trends, and supply/demand dynamics, rather than relying on social media sentiment.
- Focus on probabilities and statistical edge in trading setups, aiming for factors slightly better than 50/50 odds, rather than emotional decision-making or discretionary trading.
- Identify and analyze recurring market patterns (order flow, intraday behavior, market structure) to develop a quantitative edge, avoiding subjective interpretation.
- Understand and adapt trading strategies based on market regime changes, such as losing key moving averages (20, 50 period) or breaking important support/resistance levels.
- Develop a trading plan that includes entry/exit criteria, position sizing, and risk management rules to systematically approach the market and avoid emotional decisions.
- Focus on intraday trading to match personality and avoid mixing time horizons, specializing in one approach like short-term trades or swing trading.

Chart Analysis and Indicators

- Use indicators like Spaceman key level to identify previous day highs/lows, monthly, and weekly opens, signaling potential trend changes when price breaks through.
- Set alerts for extreme positioning changes like open interest spikes and anchored VWAP levels to identify potential trade setups where positioning may be offside.
- Use boxes instead of lines to mark zones on charts, especially in illiquid markets with high ATR, providing a better cushion for price noise.
- Monitor order book activity for large orders, sweeps, or liquidity being pulled to gauge market sentiment and potential price impact.
- Understand normal market conditions using indicators like ATR (Average True Range) and Zcore to identify anomalies, volatility, and potential mean reversion opportunities.

Market Analysis and Filtering

- Focus on liquid assets with high trading volume and consistent performance over time, rather than

chasing short-term movers lacking reliability.

- Filter assets by market cap (e.g., above \$500M), relative volume, and news catalysts (positive or negative) to find liquid, high-probability trading setups.
- Use momentum oscillators like RSI, CCI, Fisher, or stochastic RSI for alerts to identify potential trend reversals or continuations based on overbought/oversold conditions.
- Screen for overnight gappers in stocks to find assets with significant price changes between sessions, researching catalysts behind these moves.
- Combine relative volume and average true range to filter assets with increased volatility and activity, focusing on assets with ATR and daily range above 10-14%.

Technical Analysis and Alerts

- Set alerts on significant price levels to efficiently catch trading opportunities without constantly monitoring assets.
- Use TradingView to filter assets based on technical indicators like RSI and moving averages, sorting assets quickly to identify potential trading opportunities.
- Set ATR lookback period to 1 to quickly identify outlier price action on any timeframe without manual work.
- Use historical data analysis to determine average asset performance after reaching certain price levels or ranges, filtering alerts based on this data.
- Monitor high timeframe charts (daily/4-hour) for major pivots and low timeframe charts (30-minute/hourly) for entry signals, applying high timeframe levels to low timeframe charts.

Advanced Filtering and Analysis

- Set alerts on TradingView for ATR multiples (e.g., 2x the average 14/7 period ATR) to identify potential mean reversion opportunities across all timeframes.
- Filter watchlist by volume, relative volume increases, and market cap to identify liquid assets for trading, using moving averages and RSI to determine trends.
- Use Zcore and RSI to set alerts for overbought/oversold levels on desired timeframe, recording price action after interaction to identify mean reversion or breakout opportunities.
- During strong market trends, focus on top 10 assets holding above major pivots and remaining consistent, avoiding assets underperforming BTC.
- Use relative performance charts to identify top assets over desired timeframe (e.g., 1 month) and potential mean reversion opportunities at extremes, filtering by momentum conditions.

Risk Management and Best Practices

- Avoid trading through major economic events like non-farm payroll releases that can cause significant market whiplash and introduce unpredictability.
- Write down and reference weekly/daily levels, current events, and market structure to understand context and key levels before trading, using post-it notes for quick reference.
- Adjust ATR lookback period based on market conditions: use shorter period for responsive price action, longer period for smoother ATR.
- Use Aggre with sound alerts in the background to spot significant market activity changes without constantly monitoring charts.

Efficiency and Automation

- Automate background work by filtering charts for assets satisfying your trading criteria and alerts, keeping your workspace focused on current opportunities.
- Use TradingView to filter assets based on technical indicators, sorting assets by RSI or other indicators to quickly identify potential trading opportunities.
- Populate a watchlist with assets that have relative volume above a certain threshold, like 4x for XCN, to identify unusual trading activity worth investigating.
- Combine multiple indicators like Zcore, ATR, and implied volatility to filter trading opportunities around confluence events, such as spikes above certain thresholds.

Market Context and Asset Selection

- Focus on liquid assets with catalysts and market interest for intraday trading, casting a wide net but prioritizing assets meeting your trading criteria.
- Match trading style to personality for better results, focusing on lower time frame trades and capturing portions of prevailing trends if easily bored.
- Mark key market levels on charts based on significant news events that caused major market changes, serving as important reference points for trading decisions.
- Combine volume, market cap, moving averages, and RSI filters to create a focused watchlist of high-probability trading opportunities without random asset selection.
